Alternation of Generations and Multicellular, Dependent Embryos • Plants alternate between two multicellular stages, a reproductive cycle called alternation of generations . The gametophyte is haploid and produces haploid gametes by mitosis • Fusion of the gametes gives rise to the diploid sporophyte, which produces haploid spores by meiosis • The diploid embryo is retained within the tissue of the female gametophyte • Nutrients are transferred from parent to embryo through placental transfer cells • Land plants are called embryophytes because of the dependency of the embryo on the parent

Jung vs. Campbell

Why follow our \"intuition\" when it's notoriously inaccurate?

Sporophylls and Spore Variations • Sporophylls are modified leaves with sporangia • Sori are clusters of sporangia on the undersides of sporophylls • Strobili are cone-like structures formed from groups of sporophylls . Most seedless vascular plants are homosporous, producing one type of spore that develops into a bisexual gametophyte All seed plants and some seedless vascular plants are heterosporous Heterosporous species produce megaspores, which give rise to female gametophytes, and microspores, which give rise to

male gametophytes

Transport in Xylem and Phloem • Vascular plants have two types of vascular tissue: xylem and phloem • Xylem conducts most of the water and minerals and includes dead cells called tracheids • Water-conducting cells are strengthened by lignin and provide structural support • Phloem consists of living cells and distributes sugars, amino acids, and other organic products • Vascular tissue allowed for increased height, which provided an evolutionary advantage

Concept 29.1: Land plants evolved from green algae • Green algae called charophytes are the closest relatives of land plants • Many characteristics of land plants also appear in a variety of protist clades, mainly algae •

However land plants share four key traits with only charophytes: rings of cellulose-synthesizing complexes, peroxisome enzymes, structure of flagellated sperm, and formation of a phragmoplast. Comparisons of both nuclear and chloroplast genes point to charophytes as the closest living relatives of land plants. Note that land plants are not descended from modern charophytes, but share a common ancestor with modern charophytes.

The Greening of Earth • For more than the first 3 billion years of Earth's history, the terrestrial surface was lifeless • Cyanobacteria likely existed on land 1.2 billion years ago • Around 500 million years ago, small plants, fungi, and animals emerged on land • Since colonizing land, plants have diversified into roughly 290,000 living species • Land plants are defined as having terrestrial ancestors

Bryophyte Gametophytes • In all three bryophyte phyla, gametophytes are larger and longer living than sporophytes • Sporophytes are typically present only part of the time • A spore germinates into a gametophyte composed of a protonema and gamete-producing gametophore • The height of gametophytes is constrained by lack of vascular tissues • Rhizoids anchor gametophytes to substrate • Mature gametophytes produce flagellated sperm in antheridia and an egg in each archegonium • Sperm swim through a film of water to reach and fertilize the egg
